SUMMARY

In this article, the minimum time and fuel consumption of an aircraft in its climbing phase is studied. The controls are the thrust and the lift coefficient and state constraints are taken into account: air slope and speed limitations. The application of the Maximum Principle leads to parameterize the optimal control and the multipliers associated to the state constraints with the state and the costate and leads to describe a Multi-Point Boundary Value Problem which is solved by multiple shooting. This indirect method is the numerical implementation of the Maximum Principle with state-constraints and it is initialized by the direct method, both to determine the optimal structure and to obtain a satisfying initial guess. The solutions of the boundary value problems we define give extremals which satisfy necessary conditions of optimality with at most two boundary arcs. Note that the aircraft dynamics has a singular perturbation but no reduction is performed.

1. INTRODUCTION

A flight is composed of several phases which are take-off, climb, cruise, descent, approach and landing, see Figure 1. In this article, we are interested in the optimal control of an aircraft during its climbing phase. This phase is determined by its own dynamics given by an ordinary differential equation, constraints to comply with and a criterion to minimize. In this article, we consider a realistic model where the aircraft is described by its altitude $h$, its longitudinal distance $d$, the true air speed $V$, its mass $m$ and the air slope $\gamma$, and where the data, as the air density, the temperature, the pressure, the maximal thrust of the aircraft and the fuel flow, are given by two standard models,
see section 2.1. Companies are trying to optimize the cost of the flight which is a combination of fuel consumption, time of flight and some environmental issues as noise. In this study, we define the objective function by a weighted sum of the two criteria: time of flight and fuel consumption.

This climbing phase has already been studied in [2, 28] but without taking into account any operational state constraints and with different criteria. In this article, we consider limitations on the air slope (the aircraft cannot go down) and on the Mach speed, which is commonly applied to protect the structure of the aircraft. In the reference [2], the author consider a simpler model without any state constraint and gives a very detailed analysis of the singular perturbation phenomenon which arise from the air slope dynamics. It is well known that the aircraft dynamics has slow (the mass \( m \)) and fast (the air slope \( \dot{\gamma} \)) variables. The altitude \( h \) and the true air speed \( v \) are fast compare to the mass but slow compare to the air slope. This time scale separation is normally treated by a singular perturbation analysis where the solution is approximated by an asymptotic expansion. Ordinary differential equations with a singular perturbation have the particularity that the asymptotic expansion is non uniform with respect to the time. Hence, with this method, one has to consider at least two different time scales which leads to compute two different asymptotic expansions and then, in order to get a good approximation of the whole trajectory, the two asymptotic expansions has to be matched. We refer to [2, 21, 26, 29] for details about singular perturbation analysis. In [10], the same climbing phase is studied but with a simpler model and without any state constraints. The authors compare extremals of the original problem with extremals of its zero-order approximation.

In this article, we intend to proceed to the first step, i.e. computing extremals satisfying necessary conditions of optimality for the original problem, taking into account state constraints. Thus, we focus our analysis on the non-reduced optimal control problem, which is a challenging problem because of the singular perturbation, the realistic dynamics model and the state constraints. On the other hand, we make some assumptions to reduce the complexity of the dynamics. For instance, compare to [28], we assume that we are in presence of a steady and horizontal wind field. We refer to [15] for a detailed description of the aircraft dynamics.

The underlying optimal control problem is in Mayer form with a state variable of dimension five, with two controls (the lift coefficient \( C_L \) and the normalized amount of thrust \( \varepsilon \)) and two state constraints. The associated Hamiltonian is affine with respect to \( \varepsilon \) and quadratic with respect to \( C_L \). The solution of this optimal control problem can be found as an extremal solution of the maximum principle with state constraints, [19, 23, 25, 31]. The associated optimal strategy is a concatenation of boundary and interior arcs. Each type of arc is fully characterized by the application of the maximum principle and we use first a direct method to determine the structure of the optimal trajectory. Roughly speaking, the direct methods based on state and control parameterization consist in making a full discretization of the optimal control problem and then using numerical algorithms to compute candidate points which satisfy the Kuhn-Tucker conditions, see [3, 14, 33] for details. On the other hand, for a given structure, the application of the maximum principle leads to the formulation of a Multi-Point Boundary Value Problem (MPBVP). Solving the MPBVP gives an extremal which satisfies the necessary conditions of optimality. The MPBVP can be written as a set of non linear equations which are solved by a Newton-like algorithm. This is what we call indirect methods. The sensivity of Newton algorithms with respect to the initial guess is well known and we use the result from the direct method as starting guess to improve the convergence of the indirect method. Because of the phase constraints, we consider multiple shooting techniques. Each intermediate node represents the junction between two arcs. In addition, the singular perturbation is responsible for numerical difficulties and we need to add nodes on subarcs to improve numerical stability. See [7] for details about simple and multiple shooting methods.

From the numerical point of view, we have to solve a MPBVP with singular perturbation. There exists efficient dedicated methods, see [9]. The main advantage of these methods is that the choice of the mesh is based on local error and conditioning, taking into account the singular perturbation. In this article, we simply fix arbitrarily the number of nodes on each subarc (between 10 and 16) and we uniformly space them. Between two nodes, we integrate with a variable step-size Runge-Kutta scheme (\textit{radau5}, see [18]), particularly efficient for stiff problems. It would be interesting to compare these two approaches. In this study, we choose to use standard methods in optimal control
and we want to get benefit from the complementary of direct and indirect methods. We refer to [32] for a short survey of numerical direct and indirect methods for optimal control problems, with an exhaustive list of softwares established in 2009. Many efficient codes exist and we choose two open-source codes, the Bocop software [4] for the direct method and the HamPath package [8] for the indirect method. One distinctive feature of HamPath code is that it is based on the maximized Hamiltonian and the adjoint system is automatically computed by Automatic Differentiation. On the other hand, the user has to give the parameterization of the control and the multipliers (associated to the state constraints).

The paper is organized as follows. The physical model with the optimal control problem are defined in section 2. We give preliminary numerical results from the direct method at the end of this section. This gives an insight into the optimal structures. In section 3, we analyze the optimal control problem with the application of the maximum principle with phase constraints. Then numerical algorithms and results are presented in section 4. Section 5 concludes the article.

2. PHYSICAL MODEL AND MAYER OPTIMAL CONTROL PROBLEM

2.1. Aircraft performance model

In this section, the aircraft dynamics equation is presented. A non linear point-mass representation is used. An aircraft is subjected to four forces, its own weight $\vec{P}$, the Lift $\vec{L}$ which compensate the weight of the aircraft, the Thrust $\vec{T}$ which we consider colinear to the velocity vector $\vec{V}$ and the Drag force $\vec{D}$ which corresponds to friction between the aircraft and the air, see Figure 2.

The first Dynamic Principle provides the equations of motion of this aircraft with respect to $t$.

\[
\frac{dh}{dt}(t) = V(t) \sin(\gamma(t)) \\
\frac{dd}{dt}(t) = V(t) \cos(\gamma(t)) \\
m(t)\frac{dV}{dt}(t) = \varepsilon T_{\text{max}}(h(t)) - \frac{1}{2}\rho(h(t))SV(t)^2C_D(C_L) - m(t)g \sin(\gamma(t)) \\
\frac{dm}{dt}(t) = -\varepsilon C_s(V(t))T_{\text{max}}(h(t)) \\
m(t)V(t)\frac{d\gamma}{dt}(t) = \frac{1}{2}\rho(h(t))SV(t)^2C_L - m(t)g \cos(\gamma(t))
\]

The description of the parameters is given in Table I. To represent air density $\rho$, temperature $\Theta$ and pressure $P$ as smooth functions of altitude $h$, we use the smooth International Standard Atmosphere.
Parameter Description Unit
---
h Altitude m
\(d\) Longitudinal distance m
\(V\) True air speed m.s\(^{-1}\)
m Aircraft mass kg
\(\gamma\) Air slope
\(T_{\text{max}}\) Maximum thrust N
\(C_s\) Fuel flow model kg.N\(^{-1}.s^{-1}\)
S Wing area m.s\(^2\)
\(\rho\) Air density kg.m\(^{-3}\)
g Gravitational constant (assume to be constant) m.s\(^{-2}\)
\(C_L\) Lift coefficient
\(C_D\) Drag coefficient
\(\varepsilon\) Ratio of maximum thrust

Table I. Description of the data from aircraft dynamics.

\[\Theta(h) := \Theta_0 - \beta h, \quad P(h) := P_0 \left( \frac{\Theta(h)}{\Theta_0} \right)^{\frac{\gamma}{\gamma-1}} \quad \text{and} \quad \rho(h) := \frac{P(h)}{R \Theta(h)}.\]

We also use the BADA model [30] from EUROCONTROL which provides a general smooth aircraft performance model and specific values of coefficients, depending on the type of the aircraft:

\[T_{\text{max}}(h) := C_{T_1} \left( 1 - \frac{h}{C_{T_2}} + C_{T_3} h^2 \right),\]

\[C_s(V) := C_{s_1} \left( 1 + \frac{V}{C_{s_2}} \right),\]

\[C_D(C_L) := C_{D_1} + C_{D_2} C_L^2.\]

The description of the parameters from ISA and BADA models is given in Table II.

Table II. Description of the parameters from ISA and BADA models.

The aircraft evolves in a constrained context: these contraints arise from air traffic control (ATC) or physical limitations. In order to protect the structure of the aircraft its speed is limited. As it is
difficult to compute the real speed, a Computed Air Speed (CAS) which is given by a Pitot tube is used and limited by the Operation Maximal Speed (VMO), see eq. (2). Beyond a given altitude, Mach speed is usually used and limited by the Maximal Mach Operation (MMO), see eq. (3). Other constraints are coming from ATC. For example, in a climbing phase the aircraft is not allowed to go down ($\gamma \geq 0$) and to avoid the stall of the aircraft the air slope is limited ($\gamma \leq \gamma_{\text{max}}$). Only the constraints arising from the air slop and the Mach speed will be taken into account in this study:

\[\text{CAS} := \sqrt{\frac{2P_0}{\mu \rho(0)}} \left( \left( \frac{P(h)}{P_0} \left[ \frac{\mu V^2}{2R \Theta(h)} + 1 \right] \right)^{\frac{\mu}{\gamma}} - 1 \right) + 1 \right)^{\mu} - 1 \leq VMO,\]  

(2)

\[M := \frac{V}{a(h)} = \frac{V}{\sqrt{\gamma_{\text{air}} R \Theta(h)}} \leq MMO.\]  

(3)

2.2. Mayer formulation of the optimal control problem

Let note $x := (h, d, V, m, \gamma)$ the state, $M := \mathbb{R}^5$ the state space, $u := (\varepsilon, C_L)$ the control, $U := \{u = (u_1, u_2) \in \mathbb{R}^2, u_4 \in [u_{4,\text{min}}, u_{4,\text{max}}], i = 1, 2\}$ the control domain. We put all constant data in a vector $\omega$ which belongs to $\mathbb{R}^{15}$:

\[\omega := (S, g, C_{T_1}, C_{T_2}, C_{T_3}, C_{D_1}, C_{D_2}, C_{s_1}, C_{s_2}, R, \Theta_0, \beta, P_0, \mu, \gamma_{\text{air}}),\]

with $\omega_i > 0, i = 1, \ldots, 15$. The values of the parameters are given in Table III in section 2.3. The dynamics from eq. (1) can be written in the form

\[f(x(t), u(t)) := f_0(x(t)) + u_1(t)f_1(x(t)) + u_2(t)f_2(x(t)) + u_2(t)^2f_3(x(t)),\]

where $f_0, f_1, f_2$ and $f_3$ are the following smooth vector fields:

\[f_0(x) := x_3 \left( \sin(x_5) \frac{\partial}{\partial x_1} + \cos(x_5) \frac{\partial}{\partial x_2} \right) - \left( \omega_3 x_3(x, \omega) + \omega_2 \sin(x_5) \right) \frac{\partial}{\partial x_3} - \omega_2 \cos(x_5) \frac{\partial}{\partial x_5},\]

\[f_1(x) := \frac{x_3}{x_4} \frac{\partial}{\partial x_3} - \theta_1(x, \omega) \theta_2(x, \omega) \frac{\partial}{\partial x_4},\]

\[f_2(x) := \frac{\theta_2(x, \omega)}{x_3} \frac{\partial}{\partial x_5},\]

\[f_3(x) := -\omega_7 \theta_3(x, \omega) \frac{\partial}{\partial x_3},\]

and where $\theta(x, \omega) := (\theta_1(x, \omega), \theta_2(x, \omega), \theta_3(x, \omega), \theta_4(x, \omega), \theta_5(x, \omega))$ is a vector of auxiliary functions with

\[\theta_1(x, \omega) := \omega_9 \left( 1 - \frac{x_1}{\omega_4} + \omega_5 x_3^2 \right), \quad \theta_2(x, \omega) := \omega_8 \left( 1 + \frac{x_3}{\omega_9} \right), \quad \theta_3(x, \omega) := \frac{\omega_1 x_3^2}{2 \omega_1 x_4 \theta_4},\]

\[\theta_4(x, \omega) := \omega_{11} - \omega_{12} x_1,\quad \theta_5(x, \omega) := \omega_{13} \left( \frac{\theta_4}{\omega_{11}} \right)^{\frac{\omega_{10}}{\omega_{12}}}.\]

The climbing phase starts from the fixed initial state $x_0 := (h_0, d_0, V_0, m_0, \gamma_0) \in M$ and stops when the state reaches the terminal submanifold $M_f := \{x \in M, b(x) = 0\}$, with

\[b(x) := \begin{pmatrix} x_1 - x_{1,f} \\ x_2 - x_{2,f} \\ x_3 - x_{3,f} \\ x_5 - x_{5,f} \end{pmatrix},\]

where $x_{1,f}, x_{2,f}, x_{3,f}$ and $x_{5,f}$ are fixed final conditions. The final mass is free. The state constraints the aircraft has to satisfy all along the trajectory, see subsection 2.1, are put together in a vector of
constraints $c$ defined by

$$c(x) := \left( x_5, \min - x_5 \right) \frac{\psi(x) - \psi_{\max}}{v(x)}, \quad \text{with} \quad \psi(x) := \frac{x_3}{\sqrt{\omega_{1.0} \theta_1(x, \omega)}}.$$ 

The two main contributors which cost to a company during a flight are the fuel consumption and the flight duration. That is why we are interested in a mixed objective function which combines these two contributors. Finally, the optimal control problem can be summarized this way:

$$\begin{align*}
\left( \mathcal{P}_\alpha \right) & \quad \begin{cases}
g_\alpha(t, x(t)) := (1 - \alpha) (x_0 - x_4(t_f)) + \alpha t_f \to \min_{t_f, u(\cdot)} \alpha \in [0, 1] \text{ fixed}, \\
\dot{x}(t) = f(x(t), u(t)), \quad u(t) \in U, \quad t \in [0, t_f] \ a.e., \quad t_f > 0, \quad x(0) = x_0, \\
c_i(x(t)) \leq 0, \quad i = 1, 2, \quad t \in [0, t_f], \\
b(x(t_f)) = 0.
\end{cases}
\end{align*}$$

2.3. Preliminary numerical results

We give in this section some preliminary results on the structures of the trajectories for two different problems: $\alpha = 1$ (minimum time problem) and $\alpha = 0.6$, for a medium-haul aircraft, see Table III. For each problem we compare the strategies for both the state constrained and the state unconstrained cases. In the state unconstrained case, we simply remove the constraints $c_i(x(t)) \leq 0$, $i = 1, 2$. We use a direct method within the Bocop software, see section 4, to get the following numerical results. The discretisation is realised using a Gauss scheme of order 4 with 300 nodes for $\mathcal{P}_1$ and 500 nodes for $\mathcal{P}_{0.6}$. In the unconstrained cases, the initial guesses are set to look like a common climbing profile. The results of the unconstrained problem are then used as the initial guesses for the constrained problems. The following results are obtained with $m_0 = 72 000 \ kg$ for $(\mathcal{P}_1)$ and with $m_0 = 59 000 \ kg$ for $(\mathcal{P}_{0.6})$.

On Figure 3 (resp. 4), we display the values of the constraints and the controls along the trajectories solution of problem $(\mathcal{P}_1)$ (resp. $(\mathcal{P}_{0.6})$) for both cases: with and without taking into account the state constraints. We can see that the constraint on the air slope $c_5(x) := x_{5, \min} - x_5(x)$ is necessary for both problems whereas the constraint on the Mach speed $c_6(x) := \psi(x) - \psi_{\max}$ comes up only in problem $(\mathcal{P}_{0.6})$. Note that these two constraints are not active simultaneously.

Remark 1. In this paper, we restrict the theoretical study to the observations from this section.

3. ANALYSIS OF PROBLEM $(\mathcal{P}_\alpha)$ WITH MAXIMUM PRINCIPLE WITH PHASE CONSTRAINTS

3.1. Preliminary remarks

The necessary optimality conditions we are interested in are given by the maximum principle with state constraints [19, 22, 23, 31]. There are two approaches to get necessary optimality conditions: direct or indirect adjoining. Assuming we have only one single state constraint, in the direct adjoining method, this state constraint is directly adjoined to the Hamiltonian while in the indirect approach, the derivative of the constraint is adjoined. In this article, we consider the direct adjoining method since in this case, we have a direct link between the direct and indirect numerical methods. Indeed, in the indirect method (i.e. shooting method), the discretization of the parameterized multiplier associated to the state constraint gives (under some assumptions) the multipliers of the discretized optimal control problem associated to the discrete state constraints, see proposition 4.1 and Figure 6.

Another important remark is the following. According to [19], the maximum principle (in its general setting) which is commonly used when dealing with optimal control problems with state constraints has no rigorous proof in the literature. In [19], this maximum principle is referred as an
Figure 3. Evolution of the constraints and the controls along a time minimum trajectory ($\alpha = 1$) with respect to the normalized time $\bar{t}$. The red dashed lines represent problem ($P_1$) while the same problem without state constraints is represented by blue solid lines. The boundaries of state and control constraints are given by the dotted horizontal lines.

Figure 4. Evolution of the constraints and the controls along a time minimum trajectory ($\alpha = 0.6$) with respect to the normalized time $\bar{t}$. The red dashed lines represent problem ($P_{0.6}$) while the same problem without state constraints is represented by blue solid lines. The boundaries of state and control constraints are given by the dotted horizontal lines.
Let define the pseudo-Hamiltonian of the Mayer optimal control problem \((P_\alpha)\) by

\[
H : T^* M \times U \times \mathbb{R}^2 \rightarrow \mathbb{R}
\]

\[
(x, p, u, \eta) \mapsto H(x, p, u, \eta) := \langle p, f(x, u) \rangle + \langle \eta, c(x) \rangle
\]

where \(T^* M\) is the cotangent bundle of \(M\) and \(\eta\) is the Lagrange multiplier associated to the constraint vector \(c(x)\). If \((u^*(\cdot), t_f^* )\) is optimal with \(x^*(\cdot)\) the associated optimal trajectory, then assuming \(u^*(\cdot)\) is piecewise smooth, \(x^*(\cdot)\) has finitely many junction times with the constraint, and assuming the final time is not a junction time, then the maximum principle asserts that there exists a real number \(p^0\) \(\leq 0\) and a piecewise absolutely continuous costate trajectory \(p^*(\cdot)\) such that \((p^*(\cdot), p^0)\) does not vanish on \([0, t_f^*]\). Besides, there exists a function \(\eta^*(\cdot)\) such that \(\eta_i^*(t) \leq 0\) and \(\eta_i^*(t) c_i(x^*(t)) = 0, i = 1, 2, \) for all \(t\) in \([0, t_f^*]\). Moreover, we have for almost every \(t \in [0, t_f^*]\)

\[
\dot{x}^*(t) = \frac{\partial H}{\partial p}(x^*(t), p^*(t), u^*(t), \eta^*(t)), \quad \dot{p}^*(t) = -\frac{\partial H}{\partial x}(x^*(t), p^*(t), u^*(t), \eta^*(t))
\]

and we have the maximization condition

\[
H(x^*(t), p^*(t), u^*(t), \eta^*(t)) = \max_{u \in U} H(x^*(t), p^*(t), u, \eta^*(t)).
\]

The boundary conditions must be fulfilled and we have the following transversality conditions:

\[
p^*(t_f^*) = p^0 \frac{\partial g_0}{\partial x}(t_f^*, x^*(t_f^*)) + \sum_{k=1}^{4} \lambda_k b'_k(x^*(t_f^*)), \quad (\lambda_1, \ldots, \lambda_4) \in \mathbb{R}^4
\]

\(\dagger\)A junction time is either an entry or an exit time of a boundary arc. A contact time is a time when the arc has an isolated contact with the boundary.

Since the final time $t_f$ is free, if $u^*(\cdot)$ is continuous at time $t_f$, we have:

$$H[t_f^*] = -p_0 \frac{\partial g_0}{\partial t}(t_f^*, x^*(t_f^*)),$$

where $[t]$ stands for $(x^*(t), p^*(t), u^*(t), \eta^*(t))$. Let $\mathcal{T}$ denote the finite set of contact and junction times with the boundary. Then at $\tau \in \mathcal{T}$ we have

$$H[\tau^+] = H[\tau^-],$$

$$p(\tau^+) = p(\tau^-) - \nu_i \epsilon_i(x(\tau)), \quad \nu_i \in \mathbb{R}, \quad i = 1, 2.$$

**Remark 2.** Either $p_0 = 0$ (abnormal case), or $p_0$ can be set to $-1$ by homogeneity (normal case). We consider only the normal case.

**Definition 1.** We call an extremal the quadruplet $(x(\cdot), p(\cdot), u(\cdot), \eta(\cdot))$ defined on $[0, t_f]$ where $u(\cdot)$ is an admissible control\(^4\) and which satisfies eqs. (4), (5), (8), (9). Any extremal satisfying the boundary conditions and equations (6), (7) is called a BC-extremal. We define the Hamiltonian lifts $H_i(z) := \langle p, f_i(x) \rangle$, $i = 1, \ldots, 4$, $z := (x, p)$, and the function $\varphi(t) := \frac{\partial H}{\partial \alpha}(z(t), u(t), \eta(t)) = (\varphi_1(t), \varphi_2(t))$, with $\varphi_1(t) = H_1(z(t))$ and $\varphi_2(t) = H_2(z(t)) + 2u_2(t)H_3(z(t))$.

### 3.3. Adjoint equations and transversality conditions

Using conditions (4), we get the adjoint equations\(^5\):

$$\dot{p}_1 = p_3 \frac{\theta_3}{\theta_4} (\omega_2 - \omega_2 \omega_7 + u_2^2 \omega_7) - u_1 \omega_3 (p_3 x_4 - p_4 \theta_2) (-\frac{1}{\omega_4} + 2\omega_5 x_1)$$

$$- p_5 u_2 \frac{\theta_4}{x_4 \theta_4} (\omega_1 - \omega_2 \omega_7) - \langle \eta, \frac{\partial c}{\partial x_1} \rangle,$$

$$\dot{p}_2 = 0,$$

$$\dot{p}_3 = -p_1 \sin(x_5) - p_2 \cos(x_5) + 2p_3 \frac{\theta_3}{x_3} (\omega_6 + u_2^2 \omega_7) + p_4 \theta_1 \frac{\omega_2}{\omega_9} u_1$$

$$- p_5 \frac{\theta_3}{x_3} (u_2 \theta_3 + \omega_2 \cos(x_5)) - \langle \eta, \frac{\partial c}{\partial x_5} \rangle,$$

$$\dot{p}_4 = -p_3 \frac{\theta_3}{x_4} (\omega_6 + \omega_7 u_2^2) + p_3 \frac{\theta_3}{x_3 x_4} u_1 + p_5 \frac{\theta_3}{x_3 x_4} u_2 - \langle \eta, \frac{\partial c}{\partial x_5} \rangle,$$

$$\dot{p}_5 = x_3 (-p_1 \cos(x_5) + p_2 \sin(x_5)) + p_3 \omega_2 \cos(x_5) - p_5 \frac{\omega_2}{x_3} \sin(x_5) - \langle \eta, \frac{\partial c}{\partial x_5} \rangle.$$

From equations (6) and (7) we have $p_0^*(t_f^*) = p_0^*(\alpha - 1)$ and $H[t_f^*] = -p_0^*\alpha$. Since the system is autonomous, the Hamiltonian is constant along any extremal and then $H[t] = -p_0^*\alpha$, $t \in [0, t_f]$ a.e.

### 3.4. Lie bracket configuration

#### 3.4.1. Notation

If $f$ is a smooth function on $M$ and $X$ is a smooth vector field on $M$, $X$ acts on $f$ by the Lie derivative $f \mapsto X \cdot f$ with $(X \cdot f)(x) := f'(x)X(x)$. Considering two smooth vector fields $X_0$ and $X_1$, the operator $X_1 \mapsto [X_0, X_1] := X_0 \cdot X_1 - X_1 \cdot X_0$ gives the Lie bracket on vector fields. The Poisson bracket of the two Hamiltonian lifts $H_0$ and $H_1$ of $X_0$ and $X_1$ is defined by $[H_0, H_1] := \overline{H}_0 \cdot H_1$ where $\overline{H}_0 := (\partial_2 H_0, -\partial_2 H_0)$. We use the notation $H_{01}$ (resp. $X_{01}$) to denote the bracket $[H_0, H_1]$ (resp. $[X_0, X_1]$). Since $H_0$ and $H_1$ are two Hamiltonian lifts, $[H_0, H_1] = \langle p, [X_0, X_1] \rangle$.

---

\(^4\)An admissible control is a $L^\infty$-mappings on $[0, t_f]$ taking its values in $U$ such that the associated trajectory $x(\cdot)$ is globally defined on $[0, t_f]$.

\(^5\)If necessary, we omit arguments of the functions for readability.
3.4.2. Computations of Lie brackets

Let introduce the vector field

\[ f_{02}(x) = -\theta_3 \cos(x_5) \frac{\partial}{\partial x_1} + \theta_3 \sin(x_5) \frac{\partial}{\partial x_2} + \frac{\omega_2 \theta_3}{x_3} \cos(x_5) \frac{\partial}{\partial x_3} + \left( \frac{\theta_3}{\theta_4} \left( \omega_{12} - \omega_2 \omega_{10} \right) \sin(x_5) - \frac{\theta_3}{x_3^2} \left( \omega_6 \theta_3 + 2\omega_2 \sin(x_5) \right) \right) \frac{\partial}{\partial x_5}, \]

then we have the following proposition.

**Proposition 3.1.** The vector set \( \{ f_0(x), f_1(x), f_2(x), f_3(x), f_{02}(x) \} \) forms a basis of \( T_x M \) for every \( x \in M_1 := \{ x \in M, x_1 \neq \frac{\omega_1}{\omega_2}, x_1 \neq \frac{1 \pm \sqrt{1 - 4 \omega_2^2 \omega_5}}{2 \omega_2 \omega_5}, x_3 \neq 0, x_3 \neq -\omega_6, x_4 \neq 0 \} \).

**Proof**

We have \( \det(f_0(x), f_1(x), f_2(x), f_3(x), f_{02}(x)) = -\omega_7 \theta_1 \theta_2 \theta_3 \neq 0 \) for \( x \in M_1 \).

In our problem, quantities \( \theta_1, \theta_2 \) and \( \theta_3 \) could not be equal to zero due to physical considerations, so any trajectory \( x(t) \) belongs to \( M_1 \) and we can express all the Lie brackets on the basis previously defined. Brackets of order two are then

\[ f_{01} = a_{01} f_0 + b_{01} f_1 + d_{01} f_2 + e_{01} f_3, \quad f_{03} = a_{03} f_0 + d_{03} f_2 + e_{03} f_3, \]
\[ f_{21} = d_{21} f_2, \quad f_{31} = b_{31} f_1 + e_{31} f_3, \quad f_{23} = d_{23} f_2, \]

where

- \( a_{01} = -\frac{\theta_1}{x_3 x_4}, \)
- \( b_{01} = \frac{\omega_3}{\theta_1} \left( -\frac{1}{\omega_4} + 2\omega_5 x_1 \right) \sin(x_5) - \frac{1}{\theta_4} \left( \frac{\omega_8}{\omega_9} (\omega_6 \theta_3 + 2\omega_2 \sin(x_5)) \right), \)
- \( d_{01} = -\frac{2}{x_3 x_4 \theta_3} \omega_2 \cos(x_5), \)
- \( e_{01} = -\frac{2}{x_3 x_4 \omega_7} - \frac{\theta_1 \theta_2 \omega_6}{x_4 \omega_7} + \frac{1}{\omega_7} \frac{\theta_1}{\theta_4} (\omega_6 \theta_3 + 2\omega_2 \sin(x_5)) \left( \frac{1}{x_3} - \frac{\omega_8}{\omega_9} \theta_2 \right), \)
- \( a_{03} = \frac{\omega_3}{x_3}, \)
- \( d_{03} = 2 \frac{\omega_2 \omega_7}{x_3} \cos(x_5), \)
- \( e_{03} = -\omega_6 \frac{\theta_3}{x_3} + \frac{x_3}{\theta_4} \left( \frac{\omega_12}{\omega_7} - \omega_2 \omega_{10} \right) - \frac{3\omega_2}{x_3} \sin(x_5), \)
- \( d_{21} = -\frac{\theta_1}{x_4} \left( \frac{1}{x_3} + \theta_2 \right), \)
- \( b_{31} = -\frac{\omega_7 \omega_8}{\omega_9} \frac{\theta_3}{\theta_2}, \)
- \( e_{31} = -\frac{\theta_1}{x_4} \left( \theta_2 + 2 \frac{\omega_8}{x_3} + \omega_9 \theta_2 \right), \)
- \( d_{23} = \frac{\theta_3}{x_3}. \)

3.5. Parameterization of extremal curves (state unconstrained case)

Let consider first the state unconstrained case. We denote by \( \bar{u}_2(z) := -H_2(z)/2H_3(z) \), the value that cancels \( \varphi_2 \). Hence the controls that maximize the Hamiltonian are given by:

\[ u_1(z) = \begin{cases} 
  \frac{u_{1,\text{max}}}{2}, & \text{if } H_1(z) > 0, \\
  \frac{u_{1,\text{min}}}{2}, & \text{if } H_1(z) < 0, \\
  \frac{u_{1,\text{s}}(z)}{2}, & \text{if } H_1(z) = 0,
\end{cases} \]
and

\[ u_2(z) = \begin{cases} 
    u_{2,\max}, & \text{if } \bar{u}_2(z) > u_{2,\max}, \\
    u_{2,\min}, & \text{if } \bar{u}_2(z) < u_{2,\min}, \\
    \bar{u}_2(z), & \text{if } \bar{u}_2(z) \in [u_{2,\min}, u_{2,\max}],
\end{cases} \]

- if \( H_3(z) > 0 \), then \( u_2(z) = \arg \max(H(u_{2,\min}), H(u_{2,\max})) \),
- if \( H_3(z) < 0 \), then \( u_2(z) = \begin{cases} 
    u_{2,\max}, & \text{if } H_2(z) > 0, \\
    u_{2,\min}, & \text{if } H_2(z) < 0, \\
    u_{2,s}(z) \in [u_{2,\min}, u_{2,\max}], & \text{if } H_2(z) = 0.
\end{cases} \)

Along any extremal, if the control \( u(\cdot) \) belongs to the interior of the control domain \( U \) then the Legendre-Clebsch condition

\[
\frac{\partial^2 H}{\partial u^2}(z(t), u(t), \eta(t))(v, v) \leq 0, \quad \forall v \in \mathbb{R}^2, \quad \forall t \in [0, t_f],
\]

must be satisfied, i.e. \( H_3(z(t)) \leq 0 \) for all \( t \) in \([0, t_f]\).

### 3.6. Computations of controls, multipliers and junction conditions (one state constraint)

We only analyze cases we encounter in the numerical experiments. Hence, we focus our study on a scalar state constraint \( c \). We call \( \eta \) its associated multiplier.

**Definition 2.** A boundary arc associated to a state constraint \( c \), is an arc \( \gamma_c : t \mapsto \gamma_c(t) \) defined on an interval \( J = [t_1, t_2] \), not reduced to a singleton, such that \( c(\gamma_c(t)) = 0 \) for all \( t \) in \( J \).

**Definition 3.** We define the order \( m \) of the constraint \( c \) as the first integer such that a control variable appears after the \( m \)-th differentiation of \( c \) with respect to time.

#### 3.6.1. General results

**Lemma 3.2.** The state constraints \( c_{\gamma} \) and \( c_{\nu} \) are of order 1.

**Proof**

The derivative of \( \psi \) is

\[
\dot{\psi} = \sum_{i=1}^{3} \frac{\partial \psi}{\partial x_i} \dot{x}_i = \sum_{i=1}^{3} \frac{\partial \psi}{\partial x_i} \dot{x}_i + \frac{\partial \psi}{\partial x_3} \left( -\omega_6 \theta_3 - \omega_2 \sin(x_5) + u_1 \frac{\theta_1}{x_4} - u_2^2 \omega_7 \theta_3 \right)
\]

and so \( c_{\nu} = \psi - \psi_{\max} \) is of order 1. Since \( \dot{c} = \dot{x}_5 = -\frac{\omega_2}{x_3} \cos(x_5) + u_2 \frac{\theta_3(x,\omega)}{x_3} \), \( c_{\gamma} \) is of order 1.

**Lemma 3.3.** The partial derivatives of \( \psi \) are equal to:

\[
\frac{\partial \psi}{\partial x_1}(x) = \frac{x_3 \omega_1}{\theta_4 \sqrt{\omega_0 \omega_1 \theta_4}} = \frac{\omega_1}{2 \theta_4} \psi(x) \quad \text{and} \quad \frac{\partial \psi}{\partial x_3}(x) = \frac{1}{\sqrt{\omega_0 \omega_1 \theta_4}} = \frac{\psi(x)}{x_3}.
\]

We present now the general framework used to parameterize extremals with state constraints \( c \) of order 1. Since \( c \) is of order 1, we could write in a generic way, \( \dot{c} = a_0 + u_1 a_1 + u_2 a_2 + u_3^2 a_3 \) with \((a_1, a_2, a_3) \neq (0, 0, 0)\) and with \( a_0, a_1, a_2 \) and \( a_3 \) depending on \( x \).

**Lemma 3.4.** Along the boundary, \( \{H, H_1\} = H_{0i} + u_1 H_{1i} + u_2 H_{2i} + u_3^2 H_{3i} - \eta \psi f_i, \ i = 0, \ldots, 3. \)

**Proof**

Computing, \( \{H, H_1\} = H_{0i} + u_1 H_{1i} + u_2 H_{2i} + u_3^2 H_{3i} + \{\eta c, H_i\} \), with \( \{\eta c, H_i\} = c \{\eta, H_i\} - \eta \psi f_i \) as \( c = 0 \) and \( \frac{\partial \psi}{\partial p} = 0 \).

**Lemma 3.5.** Let consider \( f_\nu \), a smooth vector field. \( H_\nu = (p, f_\nu) \) its Hamiltonian lift and \( \tau \) a junction time. Then we have \( \nu, c'(x(\tau)) f_\nu(x(\tau)) = H_\nu(z(\tau^-)) - H_\nu(z(\tau^+)) \) at the junction point.
Proof
From eq. (9), we have \( p(\tau^+) = p(\tau^-) - \nu_\tau c'(x(\tau)) \) at the junction time \( \tau \). Multiplying by \( f_\nu \) leads to \( H_\nu(z(\tau^+)) = H_\nu(z(\tau^-)) - \nu_\tau c'(x(\tau)) f_\nu(x(\tau)) \).

**Lemma 3.6.** Let assume that \( \varphi_1 > 0 \) and \( \varphi_2 = 0 \) holds along the boundary arc. Then we have:

1. if \( (a_2, a_3) = (a_2, 0) \) with \( a_2 \neq 0 \) then the control \( u(x) \) is given by
   \[
   u(x) = \left( u_{1,\max}, -\frac{a_0 + u_{1,\max} a_1}{a_2} \right).
   \]
2. if \( (a_2, a_3) = (0, a_3) \) with \( a_3 \neq 0 \) and \( a_3(a_0 + u_{1,\max} a_1) < 0 \) then the control \( u(x) \) is given by
   \[
   u(x) = \left( u_{1,\max}, -\frac{a_0 + u_{1,\max} a_1}{a_3} \right).
   \]

And in both cases, the multiplier \( \eta \) associated to the constraint \( c \) is defined by
\[
\eta = \frac{1}{c' f_2 + 2u_2 f_3} \left( H_{02} + u_{1,\max} (H_{12} + 2u_2 H_{13}) + 2u_2 H_{03} + u_2^2 H_{23} + 2H_3 u_2 f \right).
\]

Proof
Since \( \varphi_1 > 0 \), \( u_1 = u_{1,\max} \). Along the boundary \( \dot{c} = a_0 + u_{1,\max} a_1 + u_2 a_2 + u_3^2 a_3 = 0 \), \( u_2 \geq 0 \), and we determine \( u_2 \) in feedback form by solving this equation. Differentiating \( \varphi_2 \) with respect to \( t \) and with Lemma 3.4, we have along the boundary arc

\[
\varphi_2 = H_{02} + u_{1,\max} (H_{12} + 2u_2 H_{13}) + 2u_2 H_{03} + u_2^2 H_{23} + 2H_3 u_2 f - \eta c' (f_2 + 2u_2 f_3) = 0.
\]

Since \( c \) is of order 1, \( c' (f_2 + 2u_2 f_3) \) never vanishes along the boundary arc, whence the result.

Remark 3. If \( \varphi_2 < 0 \), then replace \( u_{1,\max} \) by \( u_{1,\min} \) in Lemma 3.6.

Let define now the Hamiltonian \( \bar{H} \) depending only on the scalar control \( u_2 \) (\( u_1 \) is fixed):
\[
\bar{H}(x, p, u_2, \eta) := \bar{H}(x, p, (u_{1,\max}, u_2), \eta) = \bar{H}_0 + u_2 H_2 + u_2^2 H_3 + \eta c,
\]
where \( \bar{H}_0 = H_0 + u_{1,\max} H_1 \). The following lemma is due to [5, proposition 2.5].

**Lemma 3.7.** Let \( (x(\cdot), p(\cdot), u_2(\cdot), \eta(\cdot)) \) denote an extremal associated to \( \bar{H} \) defined on \( [0, t_f] \), satisfying \( \partial \bar{H} / \partial u_2 (x(t), p(t), u_2(t), \eta(t)) = 0 \), \( t \in [0, t_f] \), and assume that:

- \( \exists \alpha > 0 \), \( \partial^2 \bar{H} / \partial^2 u_2 (x(t), p(t), u_2(t), \eta(t)) \) is strictly convex on \( [0, t_f] \) (strict Legendre-Clebsch condition).
- The constraint \( c \) is of order 1 and \( \exists \beta > 0 \), \( |\partial \dot{c} / \partial u_2 (x(t), u_2(t))| \geq \beta \), \( \forall t \in [0, t_f] \).
- The trajectory has a finite set of junction times.

Then \( u_2 \) is continuous over \( [0, t_f] \) and \( \nu_\tau = 0 \).

3.6.2. Application to problem \((P_\alpha)\)

**Extremals in \( C_\gamma \).**
Under assumptions from Lemma 3.6, since \( \dot{c}_\gamma = \frac{23}{x_3} \cos(x_3) - u_2 \frac{\partial}{\partial x_3} \) with \( \frac{\partial}{\partial x_3} \neq 0 \), we have
\[
u_\tau = -\frac{\varphi_2 (\tau^+)}{\beta_3} x_3 \text{ at the entry point, } \nu_\tau = \frac{\varphi_2 (\tau^+)}{\beta_3} x_3 \text{ at the exit point.}
\]
Extremals in $C_\gamma = \{x \in M, c_\gamma(x) \neq 0, c_v(x) = 0\}$. Under assumptions from lemma 3.6, since $\dot{c}_v = \psi$ with $\frac{\omega_6}{x_3} \psi(x) \neq 0$, we have

$$u_1 = \begin{cases} u_{1,\text{max}}, & \text{if } \varphi_1 > 0, \\ u_{1,\text{min}}, & \text{if } \varphi_1 < 0, \end{cases}$$

$$u_{2,v} := \sqrt{\frac{1}{\omega_2 \theta_2} \left( \frac{x_3^2 \omega_7^2}{2 \theta_4} - \omega_2 \right) \sin(x_5) - \omega_6 \theta_3 + \frac{u_1 \theta_1}{x_4}},$$

$$\eta_v := -\frac{1}{2u_2 \omega_2 \theta_3 \frac{\partial \psi}{\partial x_3}} \left( H_{02} + u_1 (H_{12} + 2u_2 H_{13}) + 2u_2 H_{03} + u_2^2 H_{23} + 2u_2^3 H_3 \right),$$

$$\nu_r = -\frac{\varphi_2(\tau^-)}{2u_2 \omega_2 \theta_3 \frac{\partial \psi}{\partial x_3}} \text{ at the entry point, } \nu_r = -\frac{\varphi_2(\tau^+)}{2u_2 \omega_2 \theta_3 \frac{\partial \psi}{\partial x_3}} \text{ at the exit point.}$$

4. NUMERICAL METHODS AND RESULTS

In this section, we present the numerical methods used to solve problem ($P_\alpha$). Two different types of techniques are used in this study, direct and indirect approaches. The indirect methods are implemented within the HamPath package [8]. Since the optimal control is piecewise smooth, multiple shooting technique [7] is necessary to concatenate the different smooth arcs and moreover on each smooth arc, we need to add intermediate nodes to improve numerical stability arising from the singular perturbation. Direct methods [3, 14], within the Bocop software [4], are used first to determine the structure of the BC-extremal (see definition 1) and then to initialize the multiple shooting method.

The Bocop software transforms an infinite dimensional optimal control problem (OCP) into a finite dimensional optimization problem called Non Linear Problem (NLP). Full time discretization is applied to state and control variables. These techniques are generally less precise than indirect methods, but there are more robust with respect to initialization and may be used to determine the optimal structure. The discretized problem from Bocop is solved using the interior point solver Ipopt [34] with MUMPS [1] and all the derivatives are computed using automatic differentiation with ADOL-C software [35]. For the multiple shooting problem solved by HamPath, the Fortran hybrid Newton method hybrj [27] is used to solve the non linear system and all the derivatives are computed using automatic differentiation with tapenade software [20].

4.1. Numerical methods

4.1.1. A link between KKT conditions and the maximum principle with state constraints

The optimal control problem is transformed into a fixed final time one ($t = s t_f, s \in [0, 1]$):

$$\begin{align*}
(P_\alpha) & \quad \begin{cases} 
\min g(t_f(1), x(1)) \\
\dot{x}(s) = t_f(s) f(x(s), u(s)) \\
t_f(s) = 0 \\
x(0) = x_0 \text{ fixed} \\
c(x(s)) \leq 0 \\
c_u(u(s)) = (u_1(s) - u_{1,\text{max}}, -u_1(s) + u_{1,\text{min}}, u_2(s) - u_{2,\text{max}}, -u_2(s) + u_{2,\text{max}}) \leq 0 \\
b(x(1)) = 0
\end{cases}
\end{align*}$$

The Hamiltonian associated to this optimal control problem is then

$$H(x, t_f, u, p, p_{t_f}, \eta) = \langle t_f f(x, u), p \rangle + \langle \eta, c(x) \rangle,$$

and the Lagrangian associated to the Non Linear Problem ($NLP$) obtained by the discretization of the state equation by implicit Euler scheme is using the notation here $x = (x_1, \ldots, x_N)$, $u = \cdots
and adjoint state variables, we have to compute $u$

An important point is here that if we want to compute the optimal control from the state

Remark 5. Covector mapping principle) exists in the case of pseudospectral methods, see [13, 33].

well known [6, 11, 12, 16, 24] and the scheme Figure 5 commutes. A similar result (known as the

In the unconstrained case and if we don't have constraints on the control, this result is

Remark 4.

Then, if we add the conditions

conditions of the maximization of the Hamiltonian.

For the maximization of the Hamiltonian we compute

\[ \frac{\partial L}{\partial x_i}(x, t_f, u, p, \mu, \bar{\eta}, \lambda) = 0 \]

For the maximization of the Hamiltonian we compute

\[ \frac{\partial L}{\partial u_i}(x, t_f, u, p, \mu, \bar{\eta}, \lambda) = -h_t f_u(x_i, u_i) \mu_i + c_u(u_i) = 0 \quad \text{for } i = 1, \ldots, N. \]

Then, if we add the conditions $c_u(u_i) \leq 0$, $\mu_i \leq 0$ and $\langle \mu_i, c_u(u_i) \rangle = 0$, we recognize the (KKT) conditions of the maximization of the Hamiltonian.

Remark 4. In the unconstrained case and if we don’t have constraints on the control, this result is well known [6, 11, 12, 16, 24] and the scheme Figure 5 commutes. A similar result (known as the Covector mapping principle) exists in the case of pseudospectral methods, see [13, 33].

Remark 5. An important point is here that if we want to compute the optimal control from the state and adjoint state variables, we have to compute $u(x_i, p_{i-1})$ and not $u(x_i, p_i)$. See also Figure 6 to observe the difference between the Lagrange multipliers associated to the state constraint in the two cases: KKT on the NLP problem and discretization of the BVP problem.
Optimal Control Problem $\xrightarrow{\text{PMP}}$ Boundary Value Problem (BVP)

Discretization $\xrightarrow{\text{NLP}}$ KKT $\xrightarrow{\text{Discretization}}$ Nonlinear Equation

Figure 5. This scheme commutes if the discretization of the state-adjoint state equation is a partitioned Runge-Kutta and symplectic scheme [17].

Figure 6. Evolution of the multiplier $\eta_i$ associated to the constraint $c_\gamma$. The solid blue lines represent the data extracted from direct method. Data in the rough ($\tilde{\eta}_i$) are presented on the left figure whereas processed data ($\eta_i = \tilde{\eta}_i h$, with $h$ the step size) are presented on the right figure. The red dashed lines represent the multiplier from the discretization of the BVP problem (obtained with indirect method).

4.1.2. Hamiltonian associated to the constrained arc

The HamPath package computes the adjoint system by automatic differentiation from the true Hamiltonian. We need the following result which shows that one can replace the control and the multipliers by their parameterized formulations, given in section 3.6.2, in the Hamiltonian and then compute the adjoint system by differentiation, instead of doing the converse as the maximum principle indicates.

**Proposition 4.2.** Let $c(x) \leq 0$ be a scalar constraint of order 1. We define for $z := (x, p) \in T^* M$ the true Hamiltonian

$$\bar{H}_C(z) := \bar{H}(z, u_2(x), \eta(z)) = H_0(z) + u_{1,\text{max}} H_1(z) + u_2(x) H_2(z) + u_2(x)^2 H_3(z) + \eta(z) c(x)$$

with $u_2$ and $\eta$ given in section 3.6.2. Let $\bar{z} := (\bar{x}, \bar{p})$ such that $\varphi_2(\bar{z}) = 0$ and $c(\bar{x}) = 0$. Assuming $\varphi_1 > 0$, then there is exactly one extremal passing through $\bar{z}$, such that $c = 0$ and $\varphi_2 = 0$ along the extremal, and it is defined by the flow of $\bar{H}_C$.

**Proof**

First we show that the space $\Sigma := \{(x, p) \in T^* M, c(x) = 0, \varphi_2(x, p) = 0\}$ is invariant with respect to the flow of $\bar{H}_C$. Let $z(\cdot) := (x(\cdot), p(\cdot))$ be the integral curve of $\bar{H}_C$ passing through $\bar{z} := (\bar{x}, \bar{p}) \in \Sigma$ at time $t = 0$. Let define $\Gamma := (\Gamma_1, \Gamma_2) \circ z(\cdot)$ with $\Gamma_1 := c \circ \pi_x$ and $\Gamma_2 := H_2 + 2(u_2 \circ \pi_x) H_3$, with $\pi_x(x, p) = x$. For readability, we note $c$ (resp. $u_2$) instead of $c \circ \pi_x$ (resp. $u_2 \circ \pi_x$) in the following calculus. Since $\Gamma$ is differentiable, we have

$$\frac{d\Gamma_1 \circ z}{dt}(t) = (\bar{H}_C, \Gamma_1)(z(t))$$

$$= \left( \begin{array}{c} c' f \\ + (H_2 + 2u_2 H_3) \left\{ u_2, \Gamma_1 \right\} + \left\{ \eta, \Gamma_1 \right\} \end{array} \right)(z(t))$$

$$\frac{d\Gamma_2 \circ z}{dt}(t) = (\bar{H}_C, \Gamma_2)(z(t))$$
Then $\tilde{\Gamma}(t) = A(t) \Gamma(t)$, with $A(t) = \begin{pmatrix} \eta, \Gamma_1 \\ \eta, \Gamma_2 \end{pmatrix} \begin{pmatrix} u_2, H_2 \pm 2u_2 \{u_2, H_3\} \end{pmatrix} (z(t))$. Since $\Gamma(0) = 0$, $\Gamma \equiv 0$ and then $z(\cdot)$ remains in $\Sigma$. Besides,

$$
\tilde{H}_C(z) = \frac{\partial H}{\partial z} (z, u_2(x), \eta(z)) + \frac{\partial H}{\partial u_2} (z, u_2(x), \eta(z)) u'_2(x) + \frac{\partial H}{\partial \eta} (z, u_2(x), \eta(z)) \eta'(z)
$$

with

$$
\frac{\partial H}{\partial u_2} (z, u_2(x), \eta(z)) = \Gamma_2(z), \quad \frac{\partial H}{\partial \eta} (z, u_2(x), \eta(z)) = \Gamma_1(z).
$$

SO $\tilde{H}_C(z(t)) = \tilde{H}(z(t))$ as $\Gamma_1$ and $\Gamma_2$ vanish along $z(\cdot)$ and $(z(\cdot), (u_{1,\text{max}}, u_2 \circ x(\cdot)), \eta \circ z(\cdot))$ is extremal.

### 4.1.3. Multiple shooting method

We define

$$
H_+ (z) := H(z, (u_{1,\text{max}}, \bar{u}_2(z)), 0),
$$

$$
H_- (z) := H(z, (u_{1,\text{min}}, \bar{u}_2(z)), 0),
$$

$$
H_1 (z) := H(z, (u_{1,\text{max}}, u_2, \gamma(z)), \eta_1(z)),
$$

$$
H_\gamma (z) := H(z, (u_{1,\text{max}}, u_2, \gamma(z)), \eta_\gamma(z)).
$$

The different true Hamiltonians related to the unconstrained cases ($H_+, H_-)$, see section 3.5, and to the constrained cases ($H_\gamma, H_\delta$), see section 3.6.2. We define also the mapping $\exp: (t, z_0) \mapsto \exp(t \tilde{H})(z_0)$ which gives the solution at the time $t$ of the Cauchy problem $\dot{z}(s) = \tilde{H}(z(s)), z(0) = z_0$. We note $\sigma_1, \sigma_2$ an arc $\sigma_1$ followed by an arc $\sigma_2$, $\sigma_i$ denoting the projection $\pi_i(\exp(t \tilde{H}_\delta)(z_0))$ with $H_\delta \in \{ H_+, H_-, H_\gamma, H_\delta \}$.

The unconstrained case. We consider that we have only one unconstrained arc of the form $\sigma_+$. On this single arc, we need a multiple shooting technique to deal with numerical instability arising from the singular perturbation. We note $(z_t, t_t)$ the discretized points and times for multiple shooting. The times $t_i$ are fixed and defined by $t_{i+1} = t_i + \Delta t, i = 0, \ldots, N - 1$ with $\Delta t = t_f/(N + 1)$. Then the multiple shooting function

$$
S_1(p_0, t_f, z_1, \cdots, z_N)
$$

is given by the following equations.

$$
x_{1,f} = \pi_{x_1}(z(t_f, t_N, z_N)),
$$

$$
x_{2,f} = \pi_{x_2}(z(t_f, t_N, z_N)),
$$

$$
x_{3,f} = \pi_{x_3}(z(t_f, t_N, z_N)),
$$

$$
x_{5,f} = \pi_{x_5}(z(t_f, t_N, z_N)),
$$

$$
(\alpha - 1)\rho^0 = \pi_{\rho_0}(z(t_f, t_N, z_N)),
$$

$$
-\alpha \rho^0 = H_+(z(t_f, t_N, z_N)),
$$

$$
0 = z(t_1, t_0, z_0) - z_1, \quad 0 = z(t_2, t_1, z_1) - z_2, \quad \ldots, \quad 0 = z(t_N, t_{N-1}, z_{N-1}) - z_N,
$$

where $z_0 := (x_0, p_0)$, $z: (t_1, t_0, z_0) \mapsto \exp((t_1 - t_0) \tilde{H}_+)(z_0)$. A zero of $S_1$ gives a BC-extremal which satisfies the necessary conditions of the maximum principle defined in section 3.

The constrained case. We consider an extremal of the form $\sigma_+ \sigma_+ \sigma_+$ and we note $t_1 < t_2$ the switching times. From proposition 4.2 we only need to check $c_\gamma = 0$ and $\varphi_2 = 0$ at the entry-time of the boundary arc, i.e $c_\gamma(x(t_1)) = 0$ and $H_2(z(t_1)) + 2u_2\gamma(x(t_1))H_3(z(t_1)) = 0$. From lemma 3.7, the jumps at times $t_1$ and $t_2$ are zero, i.e. $\nu_{t_1} = \nu_{t_2} = 0$. Due to numerical instability, multiple shooting is also used on $[t_2, t_f]$ with $(t_{s,i}, z_{s,i})$ the discretized points and times (with $t_{s,0} = t_2$) such that $t_{s,i+1} = t_{s,i} + \Delta t$ for $i = 0, \ldots, N - 1$ with $\Delta t = (t_f - t_2)/(N + 1)$. In this case, the multiple shooting function

$$S_2 := (p_0, t_1, t_2, t_f, z_1, z_2, z_{s,1}, \ldots, z_{s,N})$$

is given by the following equations.

$$0 = c_\gamma(\pi_x(z_1)), \quad 0 = H_2(z_1) + 2u_2\gamma(\pi_x(z_1))H_3(z_1),$$

$$x_{1,f} = \pi_x(z(t_f, t_{s,N}, z_{s,N})), \quad x_{2,f} = \pi_x(z(t_f, t_{s,N}, z_{s,N})), $$

$$x_{3,f} = \pi_x(z(t_f, t_{s,N}, z_{s,N})), \quad x_{5,f} = \pi_x(z(t_f, t_{s,N}, z_{s,N})), $$

$$(\alpha - 1)p^0 = \pi_{p_4}(z(t_f, t_{s,N}, z_{s,N})), \quad -\alpha p^0 = H_+(z(t_f, t_{s,N}, z_{s,N})), $$

$$0 = z(t_1, t_0, z_0) - z_1, \quad 0 = \exp((t_2 - t_1)\tilde{H}_\gamma)(z_1) - z_2, \quad 0 = z(t_{s,1}, t_2, z_2) - z_{s,1}, $$

$$0 = z(t_{s,2}, z_{s,1} - z_{s,2}, \ldots, \quad 0 = z(t_{s,N}, t_{s,N-1}, z_{s,N-1} - z_{s,N}, $$

where $z_0 := (x_0, p_0)$, $z := (t_1, t_0, z_0) \mapsto \exp((t_1 - t_0)\tilde{H}_\gamma)(z_0)$.

A zero of $S_2$ gives a BC-extremal satisfying the necessary conditions from section 3 and of the form $\sigma_+ \sigma_+ \sigma_+$.

4.2. Numerical results

4.2.1. The problem ($P_1$)

The unconstrained case. The shooting function $S_1$ defined in section 4.1.3 is implemented with data from Table III, $N = 16$ arcs and an initial mass of $x_{0,4} = 72,000$ kg. The Newton method algorithm used to find a zero of $S_1$ is initialized by data coming from direct methods (Bocop) and presented in section 2.3. Numerical integration is performed using the variable step-size scheme radau5, see [18]. The absolute and relative tolerances, used to compute the step size, are set respectively to $10^{-14}$ and $10^{-6}$. The resulting unconstrained trajectory reaches the final manifold in $t_f = 696$ s and the aircraft consumed 964 kg of fuel. The corresponding states, adjoints, controls and constraints are displayed with solid lines on Figures 7 and 8. Let focus on Figure 7, the behavior of the altitude $h$ and of the speed $v$ are opposed at the beginning and at the end of the trajectory. At the beginning, the aircraft trades potential energy for kinetic energy in order to reach a sufficient climbing speed and at the end of the trajectory, the opposite exchange is realized in order to reach the targeted altitude. We can summarize this behaviour as an energy sharing strategy and even though this strategy fulfills the constraint $c_\gamma$, it violates the constraint $c_\gamma$.

The constrained case. The result from direct method with the constraint on $\gamma$ is given in the preliminary section 2.3, in Figure 3. From this figure, we deduce that the trajectory $\sigma^*$ is composed by a concatenation of constrained and unconstrained arc such that $\sigma^* := \sigma_+ \sigma_+ \sigma_+$. The shooting function $S_2$ defined in section 4.1.3 is then implemented with data from Table III, $N = 17$ arcs and an initial mass of $x_{0,4} = 72,000$ kg. As for the unconstrained case, the Newton method used to find a zero of $S_2$ is initialized by data from Bocop and the numerical integration is performed by radau5 code. The resulting trajectory reaches the targeted manifold in $t_f = 698$ s which is slightly superior than the unconstrained case but the aircraft still consumes around 964 kg of fuel. The red dashed lines on Figures 7 and 8 represent the constrained trajectory. The energy sharing strategy is used here at the end of the trajectory to gain potential energy and reach the targeted manifold.

4.2.2. The problem ($P_{0.6}$)
Figure 7. Problem \( (P_1) \). Evolution of the state (left) and adjoint (right) variables along the state unconstrained (blue plain lines) and the state constrained (red dashed lines) trajectories in the time minimal case with respect to the normalized time \( \bar{t} \). From top to the bottom, we display the altitude \( h \), the longitudinal distance \( d \), the speed \( v \) and the mass \( m \).
Figure 7. **Problem (P1).** Evolution of the air slope $\gamma$ (left) and its associated adjoint $p_\gamma$ (right) along the state unconstrained (blue solid lines) and the state constrained (red dashed line) trajectories with respect to the normalized time $\bar{t}$.

Figure 8. **Problem (P1).** Evolution of the constraints and the controls along the state unconstrained (blue solid lines) and state constrained (red dashed lined) trajectories with respect to the normalized time $\bar{t}$, in the time minimal case. From top left to bottom right, the constraint on the air slope ($c_\gamma$), the constraint on MACH speed ($c_v$), the thrust ratio ($u_1$) and the lift coefficient ($u_2$) are displayed. The time $t_{c_\gamma,i}$ (resp. $t_{c_\gamma,o}$) represents the entry (resp. the exit) time on the constraint $c_\gamma$. The horizontal black dotted lines represents the bounds of the constraints on the state and the control.
The unconstrained case. The result from direct method for the problem \( (P_\alpha) \) with \( \alpha = 0.6 \) in the unconstrained case is given in Figure 4 (solid lines). From this figure, the trajectory is of the form \( \sigma^* = \sigma_+\sigma_- \). In this case, the shooting function is clear. The difference from \( S_1 \) comes from the switching between \( \sigma_+ \) and \( \sigma_- \). An additional condition is given by \( H_1 = 0 \) at the switching time \( t_1 \) which is an unknown of the shooting function in this case. This new function is then implemented using data from Table III, \( N = 15 \) and with an initial mass of \( x_{4,0} = 59\,000 \) kg. The data from Bocop and the code radau5 are still used as an initial guess for the shooting method and to perform the numerical integration. The trajectory represented on Figures 9 and 10 by the blue solid lines is quite similar to the unconstrained case of the problem \( (P_1) \). It reaches the targeted manifold in \( t_f = 650 \) s with a fuel consumption of 873 kg. The observation of the Figure 10 shows that both constraints \( c_\gamma \) and \( c_\sigma \) are violated by this trajectory but never simultaneously.

The constrained case. We deduce from the figure 4 and the unconstrained case that the trajectory is a concatenation of constrained and unconstrained arc such that \( \sigma^* := \sigma_+\sigma_2\sigma_+\sigma_\gamma\sigma_- \). The corresponding shooting function is then adapted from the shooting function \( S_2 \) and is implemented using data from Table III and an initial mass of \( x_{4,0} = 59\,000 \) kg. We split the second arc \( \sigma_+ \) and the arc \( \sigma_\gamma \) in \( N_+ = 12 \) and \( N_\gamma = 10 \) subarcs in order to deal with numerical instabilities. Like the other cases, data from Bocop are used as an initial guess to find a zero of the shooting function. The red dashed lines of Figures 9 and 10 depict the resulting trajectory. The final time \( t_f = 654 \) s is slightly superior than the final time in the unconstrained case, whereas the fuel consumption of 869 kg is slightly inferior. As for the problem \( (P_1) \), the constrained trajectory from \( (P_{0.6}) \) follows the unconstrained one and the boundaries arcs do not modify the global behavior of the trajectory.

5. CONCLUSION

In this paper, the control problem of an aircraft in a climbing phase was modeled as a Mayer optimal control problem with two state constraints of order 1 and with affine and quadratic dependance with respect to the control. We have presented an approach which combines geometric analysis and numerical methods to compute candidates as minimizers which are selected among a set of extremals, solutions of a Hamiltonian system given by the maximum principle (section 3). The optimal trajectory is a concatenation of boundary and interior arcs. In section 3.6, we compute for each type of arcs we encounter in the numerical experiments, the control law, the multiplier associated to the constraint (scalar of order 1) and the jumps on the adjoint vector at junction times.

Then we combined the theoretical results with indirect and direct methods to compute solutions which satisfy necessary conditions of optimality given by the maximum principle. One can find two technical results in section 4.1. First, proposition 4.1 justifies the use of the direct method to initialize the indirect method in the case of state constrained optimal control problems. It justifies also the direct adjoining approach, see 3.1. The second result from proposition 4.2 is a key tool for the definition of the multiple shooting functions which are solved by the indirect method, see section 4.1.3. At the end, we illustrate the approach with two examples: in section 4.2.1, we give a result about the minimum time problem while in section 4.2.2, one can find a more complex trajectory of the form \( \sigma_+\sigma_\gamma\sigma_+\sigma_\sigma_\gamma\sigma_- \) in the case of a mixed criterion between time of flight and fuel consumption.

REFERENCES

The multiple shooting technique is only used along \( \sigma_+ \) since the arc \( \sigma_- \) is short.
Figure 9. **Problem \((P_{0.6})\).** Evolution of the state (left) and adjoint (right) variables along the state unconstrained (blue plain lines) and the state constrained (red dashed lines) trajectories in the mixed criterion problem \((\alpha = 0.6)\) with respect to the normalized time \(\bar{t}\).
